

## PHY132 Introduction to Physics II

### Class 5 – **Outline:**

- Ch. 22, sections 22.1-22.4
- (Note we are skipping sections 22.5 and 22.6 in this course)
- Light and Optics
- Double-Slit Interference
- The Diffraction Grating
- Single-Slit Diffraction

### Clicker Discussion Question

A laboratory experiment produces a double-slit interference pattern on a screen. The point on the screen marked with a dot is how much farther from the left slit than from the right slit?

- A.  $1.0 \lambda$
- B.  $1.5 \lambda$
- C.  $2.0 \lambda$
- D.  $2.5 \lambda$
- E.  $3.0 \lambda$

|  
Central maximum

## Class 5 Preclass Quiz on MasteringPhysics

- This was due this morning at 8:00am
- 685 students submitted the quiz on time
- 94% of students got: A **diffraction grating** is an opaque object with many closely spaced slits. (Or a smooth surface with many closely spaced rectangular mirrors, separated by black strips.)
- 96% of students got: The first experiment to show that light is a wave was **Thomas Young's double-slit experiment** (1803).
- 71% of students got: The spreading of waves behind an aperture is **more** for long wavelengths and **less** for short wavelengths.
- 73% of students got: The **narrower** the slit in a single-slit diffraction experiment, the **wider** the central maximum (all fringes get farther apart)

## Class 5 Preclass Quiz student comments/questions

- *“Huygean wavelets are theoretical, right? Are we just imagining all of the light coming from a few tiny sources of waves?”*
- **Harlow answer:** There is a proper, mathematical wave of describing how waves travel (wave equation). Huygen's wavelets are a trick for visualizing this mathematical result.
- *“In the diffraction grating section of your video, the equation  $(I_{max}) = (N^2)(I_1)$  is given for the intensity of bright fringes. Does this give the intensity of all bright fringes or just that of the central maximum?”*
- **Harlow answer:** It's all the maxima.

### Class 5 Preclass Quiz student comments/questions

- *“Why does the intensity decrease when the angle from the slit (be it single or double) increases? I mean, what is the explanation for it because I would have thought that the intensity would oscillate about  $2I$ ?”*
- **Harlow answer:** For a double-slit of infinitesimally narrow slits, it does just oscillate. For a single slit, there is a bright central maximum, then it falls off very quickly. A real double slit is a combination of both of these.

### Class 5 Preclass Quiz student comments/questions

- *“i would like to know how to prepare for this chapter for the exam/midterm like do we just remember the results and we'll do good or should we know how it got derived because the problem set 1 had stuff **THAT YOU DIDNT GO THROUGH IN LECTURES** .. like how the phase changes by  $\pi$  when light goes from higher refractive to lower.”*
- **Harlow answer:** That's a good point. I don't have time to go over everything in the lectures, but you are responsible for all the reading in these four chapters for test 1.

If the transmitted wave moves  
*slower* than the incident wave ...

... the reflected wave undergoes a  
half-cycle phase shift.

- When the index of a film is less than the index of the material beyond it (ie glass), then the half-cycle phase shift occurs for both reflections, and the wavelengths of constructive and destructive interference were as mentioned in class:

If the transmitted wave moves  
*faster* than the incident wave ...

... the reflected wave undergoes no  
phase change.

- When the index of a film is greater than the index of the material beyond it (ie glass), then the half-cycle phase shift occurs for the front surface, but not the back-surface of the film.
- This flips the constructive vs destructive equations:

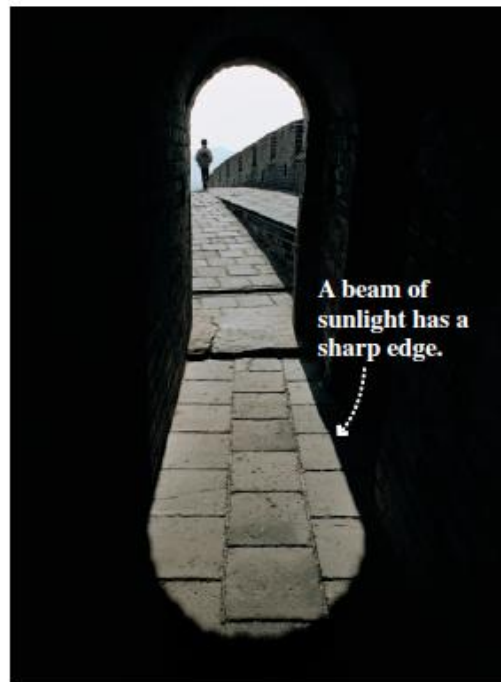

## Diffraction of Water Waves

- A water wave, after passing through an opening, *spreads out* to fill the space behind the opening
- This well-known spreading of waves is called **diffraction**

## Models of Light

- Unlike a water wave, when light passes through a large opening, it makes a sharp-edged shadow
- This lack of noticeable diffraction means that if light is a wave, the wavelength must be very small

## Diffraction of Light

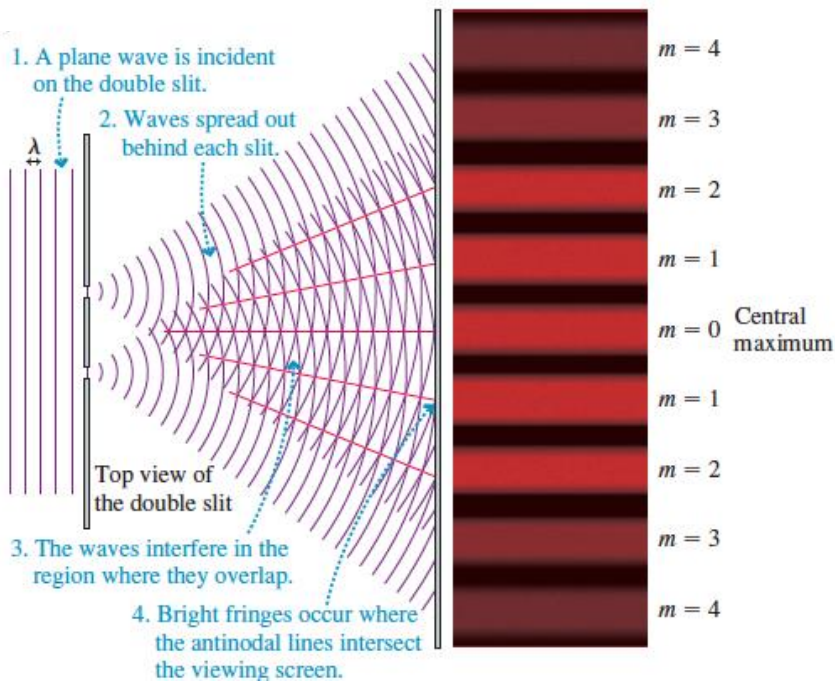

- When red light passes through an opening that is only 0.1 mm wide, it does spread out
- Diffraction of light is observable *if* the hole is sufficiently small

## Models of Light

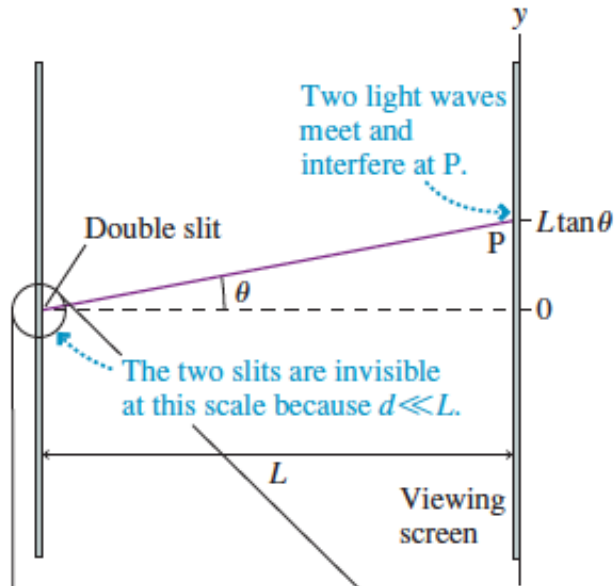

- **The wave model:** under many circumstances, light exhibits the same behavior as sound or water waves. The study of light as a wave is called *wave optics*.
- **The ray model:** The properties of prisms, mirrors, and lenses are best understood in terms of *light rays*. The ray model is the basis of *ray optics*.
- **The photon model:** In the quantum world, light behaves like neither a wave nor a particle. Instead, light consists of *photons* that have both wave-like and particle-like properties. This is the *quantum theory* of light.

## Young's Double-Slit Experiment

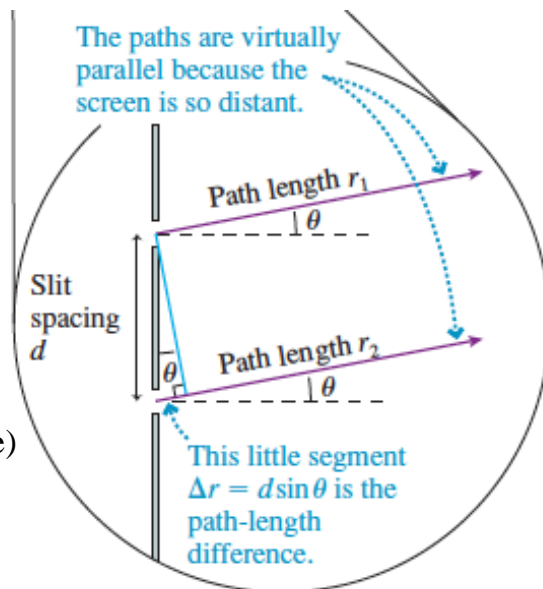

## Analyzing Double-Slit Interference

- The figure shows the “big picture” of the double-slit experiment
- The next slide zooms in on the area inside the circle

## Analyzing Double-Slit Interference

- The figure shows a magnified portion of the double-slit experiment
- The wave from the lower slit travels an extra distance
 
$$\Delta r = d \sin \theta$$
- Bright fringes (constructive interference) will occur at angles  $\theta_m$  such that  $\Delta r = m\lambda$ , where  $m = 0, 1, 2, 3, \dots$

## Analyzing Double-Slit Interference

- The  $m$ th bright fringe emerging from the double slit is at an angle

$$\theta_m = m \frac{\lambda}{d} \quad m = 0, 1, 2, 3, \dots \quad (\text{angles of bright fringes})$$

where  $\theta_m$  is in radians, and we have used the small-angle approximation

- The  $y$ -position on the screen of the  $m$ th bright fringe on a screen a distance  $L$  away is

$$y_m = \frac{m\lambda L}{d} \quad m = 0, 1, 2, 3, \dots \quad (\text{positions of bright fringes})$$

### Clicker Discussion Question

A laboratory experiment produces a double-slit interference pattern on a screen. If the screen is moved farther away from the slits, the fringes will be

- closer together.
- in the same positions.
- farther apart.
- fuzzy and out of focus.

Central maximum

### Clicker Discussion Question

A laboratory experiment produces a double-slit interference pattern on a screen. If green light is used, with everything else the same, the bright fringes will be

- A. closer together.
- B. in the same positions.
- C. farther apart.
- D. There will be no fringes because the conditions for interference won't be satisfied.

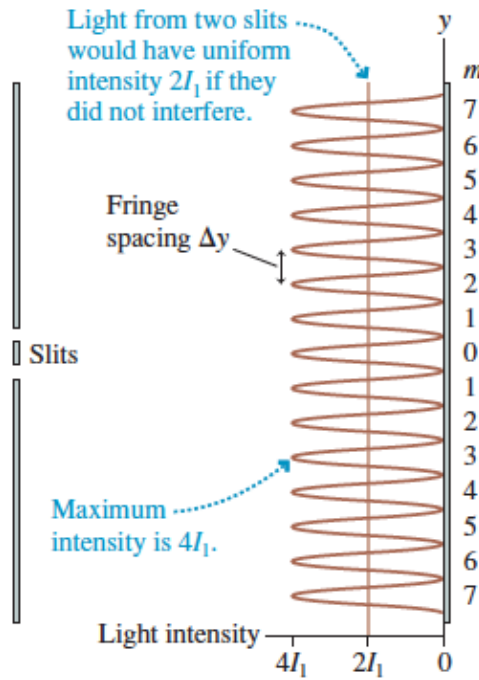

### Clicker Discussion Question

A laboratory experiment produces a double-slit interference pattern on a screen. If the slits are moved closer together, the bright fringes will be

- A. closer together.
- B. in the same positions.
- C. farther apart.
- D. There will be no fringes because the conditions for interference won't be satisfied.

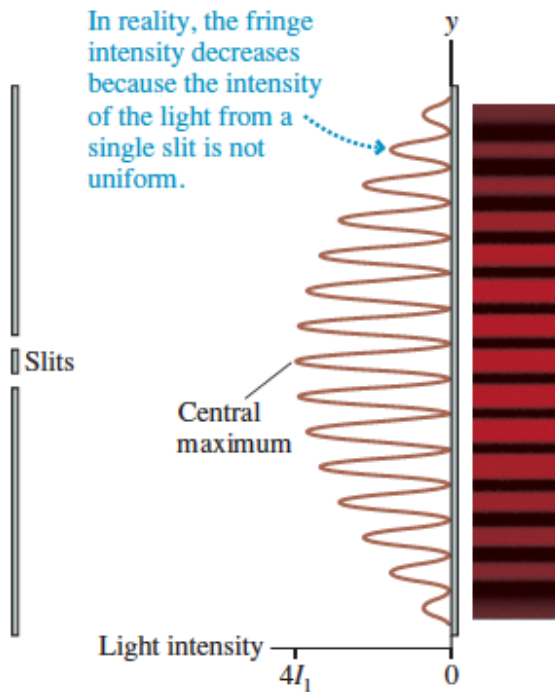

## Intensity of the Double-Slit Interference Pattern

The intensity of the double-slit interference pattern at position  $y$  is:

$$I_{\text{double}} = 4I_1 \cos^2\left(\frac{\pi d}{\lambda L} y\right)$$

## Intensity of the Double-Slit Interference Pattern

The actual intensity from a double-slit experiment slowly decreases as  $|y|$  increases.

## The Diffraction Grating

- Suppose we were to replace the double slit with an opaque screen that has  $N$  closely spaced slits
- When illuminated from one side, each of these slits becomes the source of a light wave that diffracts, or spreads out, behind the slit
- Such a multi-slit device is called a **diffraction grating**
- Bright fringes will occur at angles  $\theta_m$ , such that:

$$d \sin \theta_m = m \lambda \quad m = 0, 1, 2, 3, \dots$$

- The  $y$ -positions of these fringes will occur at:

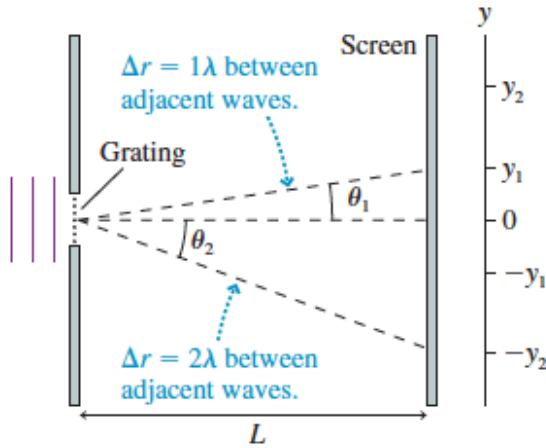

$$y_m = L \tan \theta_m \quad (\text{positions of bright fringes})$$

## The Diffraction Grating

- Suppose we were to replace the double slit with an opaque screen that has  $N$  closely spaced slits
- When illuminated from one side, each of these slits becomes the source of a light wave that diffracts, or spreads out, behind the slit
- Such a multi-slit device is called a **diffraction grating**

## The Diffraction Grating

Bright fringes will occur at angles  $\theta_m$ , such that

$$d \sin \theta_m = m\lambda$$

where  $m = 0, 1, 2, 3, \dots$

The  $y$ -positions of these fringes are:

$$y_m = L \tan \theta_m \quad (\text{positions of bright fringes})$$

## The Diffraction Grating

- The integer  $m$  is called the **order** of the diffraction
- The wave amplitude at the points of constructive interference is  $Na$
- Because intensity depends on the square of the amplitude, the intensities of the bright fringes are

$$I_{\max} = N^2 I_1$$

## The Diffraction Grating

- Diffraction gratings are used for measuring the wavelengths of light
- If the incident light consists of two slightly different wavelengths, each wavelength will be diffracted at a slightly different angle

### Clicker Discussion Question

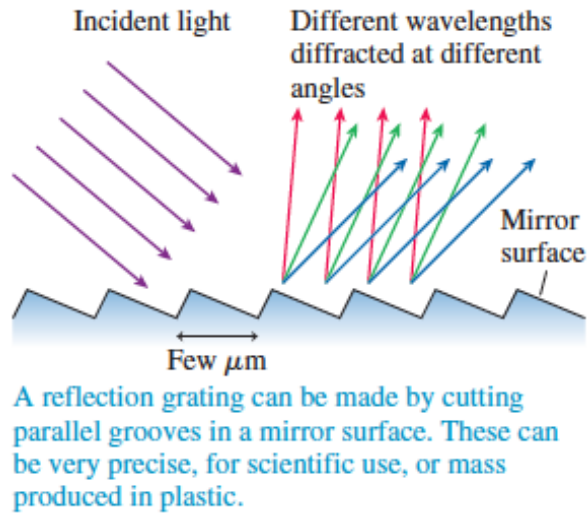

In a laboratory experiment, a diffraction grating produces an interference pattern on a screen. If the number of slits in the grating is increased, with everything else (including the slit spacing) the same, then

- The fringes stay the same brightness and get closer together.
- The fringes stay the same brightness and get farther apart.
- The fringes stay in the same positions but get brighter and narrower.
- The fringes stay in the same positions but get dimmer and wider.
- The fringes get brighter, narrower, and closer together.

## Reflection Gratings

- In practice, most diffraction gratings are manufactured as *reflection gratings*
- The interference pattern is exactly the same as the interference pattern of light transmitted through  $N$  parallel slits

## Reflection Gratings

- Naturally occurring reflection gratings are responsible for some forms of color in nature
- A peacock feather consists of nearly parallel rods of melanin, which act as a reflection grating

## Single-Slit Diffraction

- Diffraction through a tall, narrow slit is known as single-slit diffraction
- A viewing screen is placed distance  $L$  behind the slit of width  $a$ , and we will assume that  $L \gg a$

## Huygens' Principle: Plane Waves

## Analyzing Single-Slit Diffraction

Greatly magnified view of slit

The wavelets from each point on the initial wave front overlap and interfere, creating a diffraction pattern on the screen.

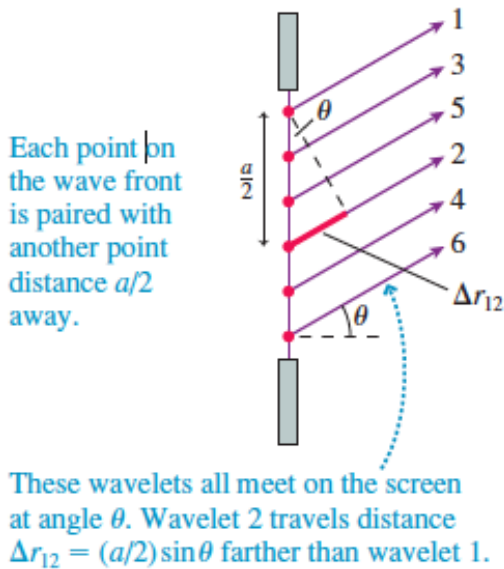

- The figure shows a wave front passing through a narrow slit of width  $a$
- According to Huygens' principle, each point on the wave front can be thought of as the source of a spherical wavelet

## Analyzing Single-Slit Diffraction

The wavelets going straight forward all travel the same distance to the screen. Thus they arrive in phase and interfere constructively to produce the central maximum.

- The figure shows the paths of several wavelets that travel straight ahead to the central point on the screen
- The screen is *very* far to the right in this magnified view of the slit
- The paths are very nearly parallel to each other, thus all the wavelets travel the same distance and arrive at the screen *in phase* with each other

- In this figure, wavelets 1 and 2 start from points that are  $a/2$  apart
- Every point on the wave front can be paired with another point distance  $a/2$  away
- If the path-length difference is  $\Delta r = \lambda/2$ , the wavelets arrive at the screen out of phase and interfere destructively

## Single-Slit Diffraction

- The light pattern from a single slit consists of a *central maximum* flanked by a series of weaker **secondary maxima** and dark fringes
- The dark fringes occur at angles:

$$\theta_p = p \frac{\lambda}{a} \quad p = 1, 2, 3, \dots \quad (\text{angles of dark fringes})$$

## The Width of a Single-Slit Diffraction Pattern

- The central maximum of this single-slit diffraction pattern is much brighter than the secondary maximum
- The width of the central maximum on a screen a distance  $L$  away is *twice* the spacing between the dark fringes on either side:

$$w = \frac{2\lambda L}{a} \quad (\text{single slit})$$

- The farther away from the screen (larger  $L$ ), the wider the pattern of light becomes
- The narrower the opening (smaller  $a$ ), the wider the pattern of light becomes!

### Clicker Discussion Question

A laboratory experiment produces a single-slit diffraction pattern on a screen. If the slit is made narrower, the bright fringes will be

- closer together.
- in the same positions.
- farther apart.
- There will be no fringes because the conditions for diffraction won't be satisfied.

## Clicker Discussion Question

A laboratory experiment produces a double-slit interference pattern on a screen. If the left slit is blocked, the screen will look like

- A. 
- B. 
- C. 
- D. 

## Before Class 6 on Wednesday

- Please read Knight Ch. 23, sections 23.1-23.5
- Please do the short pre-class quiz on MasteringPhysics by Wednesday morning at the latest.
- Something to think about:  
Is it possible to see a ray of light if it does not actually enter your eye?
